The proposed research will focus on the physiological, anatomical and functional interactions between specialized placental organs involved in the exchange of nutrient, gases, and wastes. This exchange, of vital importance to all mammalian species, will be addressed from the pregnant ewe through the neonatal pig. The hypothesis to be addressed is that specific mechanisms operating in the fetal and maternal blood vessels and placenta are altered by high levels of oxygen exposure during the late gestation period. The specific aims are: 1) to determine the effects of oxygen-induced lung hypertension on maternal and placental arterial pressure; 2) to determine the effects of chronic high oxygen levels (70% oxygen) on maternal and fetal arterial pressure and heart rate and on fetal organ blood flow and the production of fetal metabolic intermediates; 3) to determine the acute effects of oxygen exposure (70% oxygen) on maternal, placental,

and fetal cellular ionic transport, substrate transport, and cellular metabolic activities and the ability of these tissues to regulate ion concentrations; 4) to determine the effects of chronic oxygen exposure on maternal, placental, and fetal cationic transport activities, and on the ability of these tissues to regulate concentrations of ions
